## Portuguese Life Table

2017 - 2019

---

### **Life expectancy was 80.93 years at birth and 19.61 years at age 65**

**Life expectancy at birth** was estimated at 80.93 years. In 2017-2019, men and women could expect to live up to 77.95 years and 83.51 years, respectively. Compared with 2016-2018, it represents an increase of about 2 months for men and 1 month for women.

Within a decade, there was a gain of 1.99 years of life for the total population, 2.11 years for men and 1.64 years for women. This increase in female life expectancy at birth resulted mainly from a reduction in mortality among those aged 60 years and over. For men, these gains were mainly due to the decrease of mortality below 60 years.

**Life expectancy at age 65** attained 19.61 years for the total population. A man aged 65 years could expect to live another 17.70 years, and a woman aged 65 another 21.00 years, which represents a gain of 1.22 years and 1.26 years, respectively, in the last ten years.

---

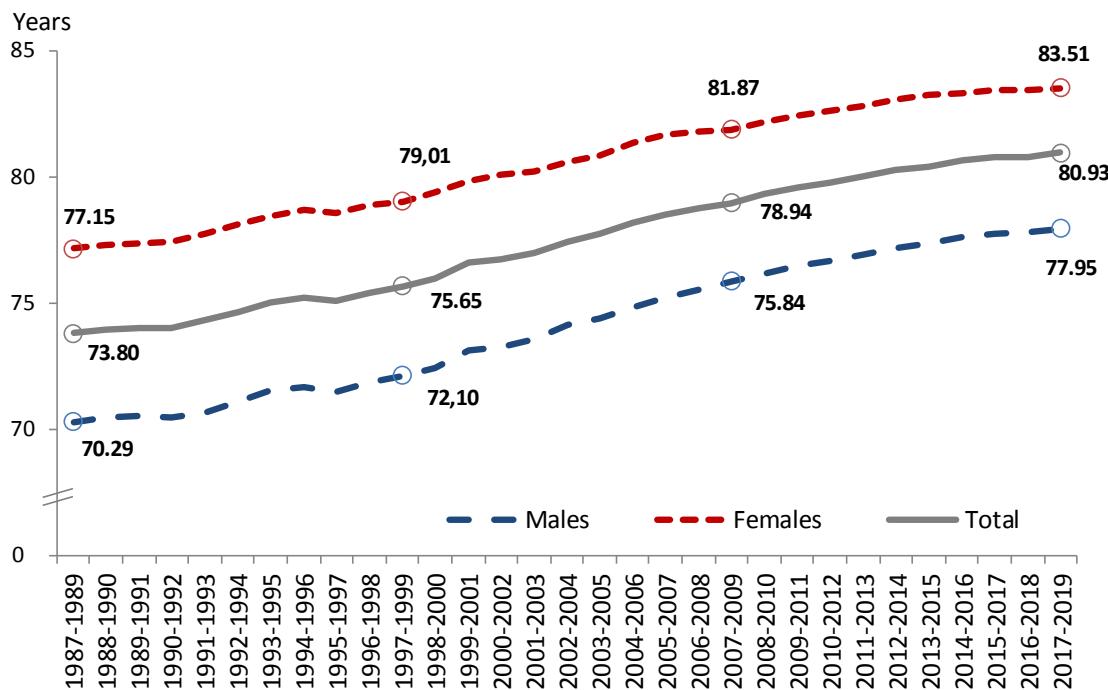

Statistics Portugal releases the 2017-2019 complete life tables for Portugal, by sex and for the total resident population, providing the official values of life expectancy for the same period.

#### **Life expectancy at birth increased to 80.93 years**

Life expectancy at birth for both males and females was estimated at 80.93 years. At birth, men and women could expect to live up to 77.95 years and 83.51 years respectively. Compared to the estimated values for 2016-2018, it represents an increase of 0.17 years (2.04 months) and 0.08 years (0.96 months), respectively, and a rise in longevity gains compared to 2016-2018 (0.48 and 0.24 months, respectively, for men and women).

In the last decade, life expectancy at birth in Portugal has increased by 1.99 years, an increase of 2.11 years for males and 1.64 years for females, when compared with the values for 2007–2009 (75.84 and 81.87 years, respectively).

## Life expectancy at birth, Portugal, 1987-1989 to 2017-2019

The increase in female life expectancy at birth over the last ten years resulted mainly from a reduction in mortality among those aged 60 years and over. For men, the increase in life expectancy at birth was mainly due to the reduction of mortality below 60 years, particularly among those aged 35 to 54<sup>1</sup>.

Women continue to live longer than men, but the gap has been gradually narrowing, from 6.03 years in 2007-2009 to 5.56 years in 2017-2019.

In 2017-2019, it is estimated that 37.6% of male live births and 58.6% of female live births will survive to age 85 if they experience the respective age-specific mortality rates of this time period for the rest of their life. In 2007-2009, these values were, respectively, 29.9% and 50.6%, for men and women<sup>2</sup>.

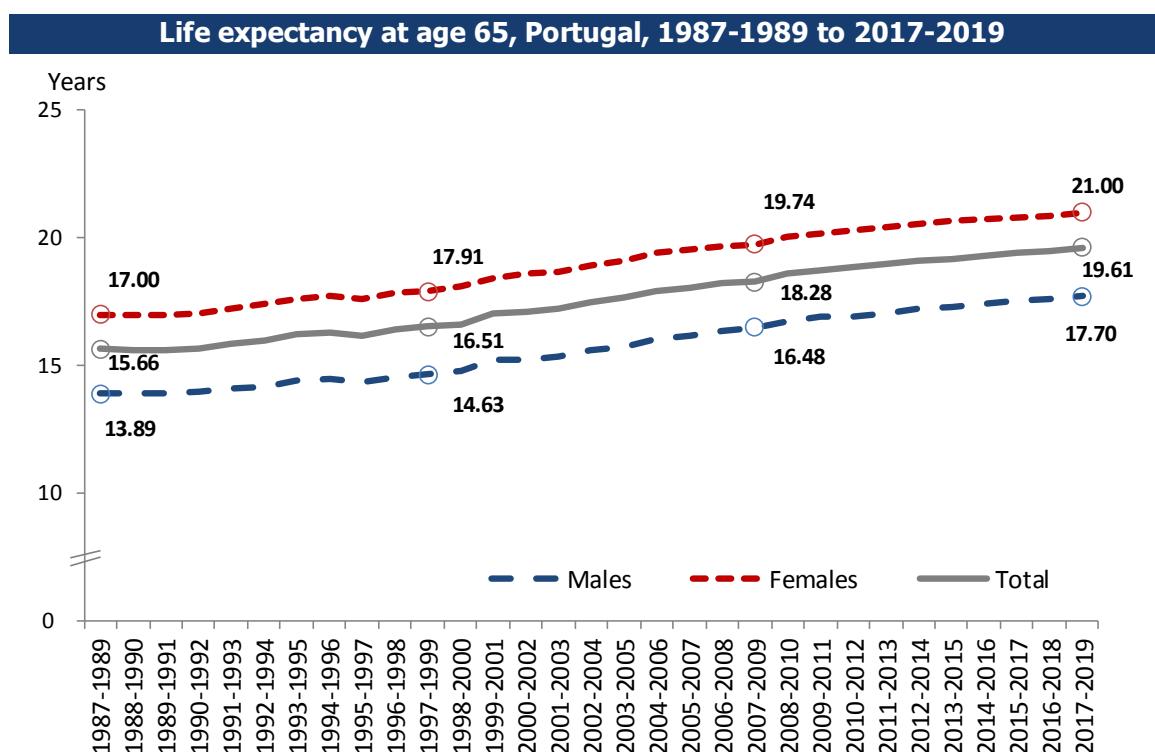

<sup>1</sup> Results based on the decomposition of the difference in life expectancy at birth between 2007-2009 and 2017-2019 (see technical note).

<sup>2</sup> Values are taken from the survival function ( $I_x$ ) of the life table (see technical note).

## Life expectancy at age 65 increased to 19.61 years

Life expectancy at age 65 attained 19.61 years for the total population, 17.70 years for men and 21.00 for women. In 2017-2019 the increase in life expectancy at age 65 was the same for both men and women (+ 0.12 years, that is, 1.44 months), thus maintaining the gap of 3.30 years between males and females compared to the estimated values for 2016-2018.

Over the last ten years, life expectancy at age 65 has risen by 1.22 years for males and by 1.26 years for females.

In 2017-2019, the majority of all deaths (65.8%) occurred among those aged 80 years and over. Approximately half of deaths for men (55.7%) and about three quarters for women (75.4%) concentrated in that age group. The most common age at death was 86 for men and 88 years for women. Ten years ago, it was 85 years for men and 87 for women<sup>3</sup>.

<sup>3</sup> Death values considered here are taken from the life table function  $d_x$  (see technical note).

## Technical note:

The life table is a mathematical model of demographic analysis composed by a set of functions which provide a basis for measuring longevity in a given population and for making probabilistic judgments about the evolution of mortality with age and time. It is based on age-specific probabilities of dying estimates obtained from the observed number of deaths and the estimated population exposed to the risk of death in a given period of time, for which it is a period life table. Thus, the life table functions represent the experience of a hypothetical cohort of 100,000 live births (called the radix of the table) through their entire life under the assumption that they are subject to the observed schedule of age-specific mortality rates in a given period of time. The life table for Portugal is referred to as a complete since it contains data for every single year of age from birth to the last applicable age.

The functions of the complete life table are:

- Probability of dying ( $qx$ ): Probability that a person aged  $x$  exactly will die before reaching age  $(x + 1)$ ;
- Survivors at exact age  $x$  ( $lx$ ): Number of survivors to exact age  $x$  of the initial cohort of 100,000 live births (radix of the table);
- Deaths between the exact ages  $x$  and  $(x + 1)$  ( $dx$ ): Number of the initial cohort dying between the exact ages  $x$  and  $(x + 1)$ ;
- Person-years lived between exact ages  $x$  and  $(x + 1)$  ( $Lx$ ): Number of person-years lived by the survivors of the initial cohort between exact ages  $x$  and  $(x + 1)$ ;
- Person-years lived above age  $x$  ( $Tx$ ): Total number of person-years lived by survivors after age  $x$ ;
- Life expectancy at age  $x$  ( $ex$ ): The average number of years a person can expect to live from exact age  $x$ .

The Complete Life Table for Portugal, which is produced annually, has a reference period of 3 years. The calculation of age-specific probabilities of dying is based on the number of deaths for a period of three consecutive years and the respective estimates for the population exposed-to-the risk of death. Due to the variability in the probabilities of dying at advanced ages (over 85 years) the method proposed by Denuit and Goderniaux (2005) is applied for smoothing and extrapolation to the last applicable age (closing age of the life table).

Life expectancy at birth, one of the most important longevity indicators provided by the life table, is a well-known summary measure of mortality, widely employed in comparisons through time and between populations. When analysing changes in life expectancy at birth or studying differences in life expectancy between two populations, it is useful to estimate the contributions of the various age groups that explain them. In the present exercise, the variation of life expectancy values at birth between 2006-2008 and 2016-2018 was analysed using the method proposed by Andreev, E. M., Shkolnikov, V. M., & Begun, A. (2002).

## Definitions:

**Life expectancy at birth:** The mean number of years that a newborn child can expect to live if subjected throughout his life to the current mortality conditions (age specific probabilities of dying).

**Life expectancy at age 65:** The mean number of years still to be lived by a person who has reached the exact age 65, if subjected throughout the rest of his life to the current age specific probabilities of dying.
